

1. A tiny web of 4 pages

D has no out-links
= a 'dangling node'

2. Its link matrix P (column j = how page j splits its vote)

	from A	B	C	D
to A	0.00	0.00	1.00	0.00
to B	0.50	0.00	0.00	0.00
to C	0.50	0.50	0.00	0.00
to D	0.00	0.50	0.00	0.00

Each column adds to 1: a page splits its vote equally among its out-links.
Column D is all zeros - D links nowhere.

3. The answer: A wins - even though C has MORE links pointing at it

C has 2 in-links, A has only 1. But C's single out-link gives ALL of C's score to A, while A splits its score two ways. PageRank measures WHO links to you, not how many.
